How do airbags produce nitrogen gas?

Today's airbags use a different chemical to produce nitrogen gas: guanidinium nitrate, plus a copper nitrate oxidizer. When ignited, guanidinium nitrate decomposes into nitrogen gas, water, and carbon. The copper nitrate oxidizer reduces the temperature of the exhaust gas, according to Blomquist.

Does airbag nitrate combust?

The propellant plays a crucial role in airbag deployment. Ammonium nitrate should combust quickly and produce a non-toxic gas, inflating the airbag in milliseconds. However, when exposed to humidity and temperature fluctuations, this chemical can deteriorate.

Is ammonium nitrate dangerous in airbag inflators?

Various studies and reports reveal critical issues surrounding airbag failures that impact millions of vehicles. Research highlights the inherent dangers of ammonium nitrate in airbag inflators.

Why do airbags explode?

These airbags utilize ammonium nitrate as an inflator. In certain conditions, this chemical can degrade, leading to uncontrollable explosions during deployment. Humidity Exposure: Long-term exposure to high humidity causes ammonium nitrate to break down, increasing the risk of combustion.

How did airbags get inflated?

The first automotive airbags developed in the 1970s employed a solid propellant. These airbag inflation systems reacted sodium azide (NaN_3) with potassium nitrate (KNO_3) in order to produce nitrogen gas. Hot blasts of nitrogen gas inflated the airbag.

What chemical reaction drives first-generation airbags?

When ignited, sodium azide forms nitrogen gas and sodium metal, which reacts with potassium nitrate and silicon dioxide additives to produce potassium silicate and sodium silicate. These are the chemical reactions that drove first-generation airbags.
